

Human–AI cowork

How one person and two AI agents share one repository

Companion to `SOP_HUMAN_AI_COWORK.md`

Three parties

The two agents never read each other's conversation. Everything one needs from the other has to be written into the repository.

One shared directory

- A branch does not protect an unsaved file
- `git add -A` commits the other agent's work
- `stash`, `restore`, `clean` destroy it

Nothing reports the loss, and nothing can recover it.

Separate worktrees

The same disagreement still happens. It now arrives as a merge conflict, which is loud, located, and recoverable, instead of as an edit that quietly disappeared.

One approval list

Read the file, take the number it says is next, and write the proposal into it in the same message that asks. This is the one step that stays synchronous.

Naming a thing

- Names a reader sees need approval first
- Loop variables and temporaries do not
- Silence is not approval

A term passes only if someone new understands it without a glossary. If it needs the explanation, it is replaced by the explanation.

Commits between agents

- One subject per commit
- The message says why, not only what
- Stage explicit paths, never everything

No separate record is kept, because Git history already is one.

Who decides

Human

names a reader sees
which side is right
what may be deleted
merging a branch

Agent

reads and inventories
proposes with a number
implements once approved
reports what it ran

Checks

duplicate numbers
unregistered files
source changed by a test
digests that drifted

*An agent that must ask about everything is useless, and one that may decide anything is unsafe.
Both lists are kept short on purpose.*

Checks bind

- An agent here ran Git against a prohibition
- The style checker gave seventeen false reports
- A check that cries wolf is soon ignored

Fixing the check is part of the work, and the fix is reported.

Takeaway

**One desk each, one list of decisions,
one history both agents can read.**

The human decides. The checks bind.
